TITLE OF THE INVENTION

CampusLoop Browser-Local Student Item Rental Request System

APPLICANT (S)

PREAMBLE TO THE DESCRIPTION: -

THE FOLLOWING SPECIFICATION PARTICULARLY DESCRIBES THE NATURE OF THE INVENTION AND THE MANNER IN WHICH IS TO BE PERFORMED

COMPLETE

1) Field of the Invention: -

CampusLoop concerns the handling of short-term item-rental requests in a campus setting. The present implementation runs in a browser. It checks dates and item availability, restricts booking actions by the selected sample user's role, and retains the demonstration state locally between page visits.

2) Background of the Innovation: -

A student may need a calculator, a camera or a cycle for only a few days. A conversation over messages can arrange the handoff, but it does not give both sides a clear record of the item, dates, estimated charge and return status. CampusLoop brings those details into one interface for a classroom demonstration. It uses switchable sample profiles, so it does not verify student identities or coordinate requests across devices. Marketplaces and booking calendars already address related problems; this draft does not treat the general idea of peer rental as new.

3) Summary of the Invention: -

The demonstrator brings together a React user interface, a marketplace state module and browser localStorage. The initial state contains sample users, listings and bookings. When a profile submits a request, the state module checks the selected item, the renter, the date interval and any active booking for the same item. It then calculates an estimated rent and records a Pending request. Later status changes depend on whether the selected profile matches the stored owner or renter. These operations take place in one browser; the interface does not collect rent or deposits.

4) Prior Art Search: -

This college draft is based on the working CampusLoop prototype. The team has not completed a comprehensive search of patent documents and publications. Campus marketplaces, reservation systems and client-side workflow tools may already disclose similar elements. The illustrative claims that follow therefore describe the implementation; they are not a finding of novelty or patent eligibility.

5) Brief Description of Drawing: -

Drawing 1 of 1 groups the implementation into input, validation, booking, status, control and storage blocks. Numbered steps trace a request from profile selection to a Pending record and show where role checks, listing restrictions and persistence apply. No server, verified-account service, shared database or payment processor is shown because none is implemented in the demonstrator.

6) Detailed Description of the Invention: -

The state object contains users, items, bookings, a currentUserId and a schema version. An item records its owner, description, category, condition, daily price, approximate value and availability. A booking records the item and renter, start and end dates, inclusive duration, estimated rent, status and creation time. The user records are sample profiles that a presenter can switch between; they are not authenticated accounts.

1. Request Validation

The request function first locates the item and selected renter. It stops if the item is missing or paused, the renter is unknown, or the renter owns that item. It also rejects a start date in the past, an end date before the start, and a period longer than 30 days when both endpoints are counted. An active booking means one in Pending, Confirmed or Return requested status. Two bookings overlap when the proposed start is on or before the existing end and the proposed end is on or after the existing start. If either test fails, no booking is added. Otherwise the function multiplies the inclusive day count by the listed daily price. For example, a three-day request at INR 20 per day yields an INR 60 estimate.

2. Booking State Transitions

A new request starts in Pending status. Its owner may confirm or decline it; its renter may cancel it. Once confirmed, the renter may request a return and the owner may cancel. Only the owner can complete a Return requested booking. Before each change, the state module derives the actor's role from the booking's renter identifier and the item's owner identifier. A button press alone does not grant that role.

3. Listing and Rating Controls

The listing form checks the title and description lengths, category, condition, daily price and approximate value before adding an item. An owner may pause a listing, but only after its active requests have been resolved. After a booking reaches Completed status, its renter may give one whole-number rating from 1 to 5. Other profiles cannot rate that booking.

4. Browser-Local Persistence

The application saves its versioned state as JSON in localStorage. On startup it loads a compatible saved state; if that data is missing or damaged, it uses the seeded sample state. The Reset demo control restores that seed deliberately. Local storage helps a presenter continue a walkthrough in the same browser. It cannot keep availability consistent between two devices or protect records against changes made in the browser.

7) Object of the Invention: -

The immediate purpose is to make the borrower and owner journeys inspectable in a classroom while keeping the sample records internally consistent. A service used by independent students would need verified accounts, shared storage, server-side authorization, moderation and agreed handoff rules. The present browser-only build does not provide those facilities.

8) Obviousness: -

Catalogs, reservation forms and status-based workflows are familiar software patterns. CampusLoop combines them for a particular demonstration: one selected profile acts on a saved booking state, and the same validation module checks dates, ownership and permitted transitions. Whether that combination involves an inventive step has not been assessed here.

9) Non-Obviousness: -

The overlap predicate and role checks are described in enough detail to explain how the demo works. That description should not be mistaken for proof that the implementation is non-obvious. Such an assessment would require relevant prior art and a comparison of the actual technical contribution, if any.

10) Novelty: -

This draft makes no novelty claim. A documented prior-art search would be needed before identifying any feature that is genuinely distinguishable. Since the system implements a software-mediated rental workflow, eligibility under section 3(k) of the Indian Patents Act would also require specialist review.

11) Industrial Applications: -

In its present form, CampusLoop supports a supervised project demonstration. A campus-wide deployment could use the same interface ideas only after adding identity checks, a shared transactional store, privacy safeguards, and procedures for handoff, damage and disputes.

I/we claim :

Claim 1 (System): A browser-executed demonstration system having a sample item catalog, a selectable sample-user profile, request validation, booking status control and local state storage, wherein request validation rejects an item owned by the selected renter and rejects a date interval that overlaps an active booking for the same item.

Claim 2 (Date Validation): The system of Claim 1, wherein the start and end dates are both counted in the rental duration, an end date preceding the start date is rejected, and the duration is limited to 30 days.

Claim 3 (Active Booking): The system of Claim 1, wherein bookings in Pending, Confirmed or Return requested status are treated as active when checking for an overlap.

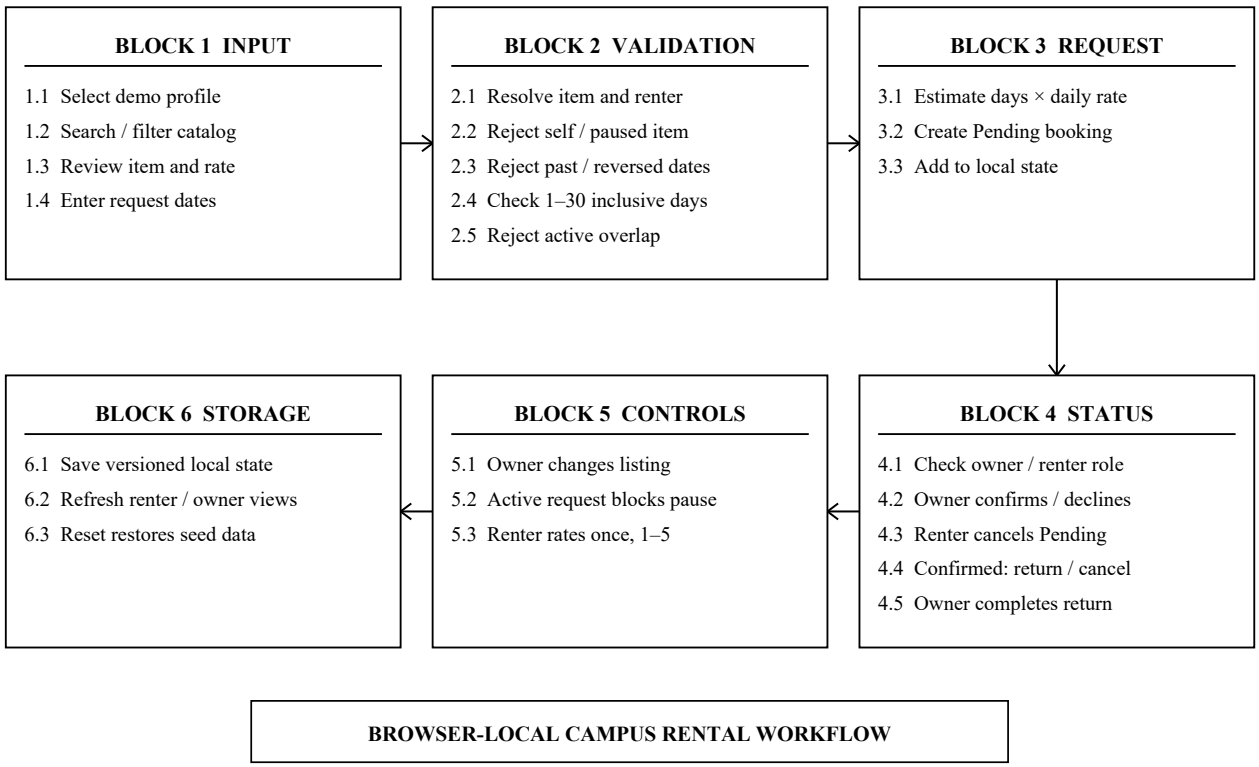

Claim 4 (Role Gate): The system of Claim 1, wherein the selected profile is compared with stored owner and renter identifiers before a booking status change is accepted.

Claim 5 (Listing Control): The system of Claim 1, wherein pausing an item is refused while an active booking for that item remains.

Claim 6 (Rating): The system of Claim 1, wherein the renter may submit one integer rating from 1 to 5 after the booking reaches Completed status.

Abstract:

CampusLoop records sample item-rental requests between selected student profiles in one browser. Its interface brings together item details, dates, an estimated rent, owner decisions and return actions. The marketplace module counts both endpoints of a rental period, checks for active date conflicts, prevents a profile from booking its own item, and applies booking transitions according to stored owner and renter identifiers. The versioned demonstration state is saved in localStorage. This classroom prototype does not authenticate users, synchronize devices or process payments.
